■ ABOUT THIS GUIDE

This guide is a rigorous companion to Module 1. All data reflects real 2026 market conditions. Read the Executive Summary before the videos, use Sections 4–8 alongside the slides to consolidate your understanding.

01 · How to Use This Guide

This guide is a concise companion to Module 1, reflecting real 2026 market conditions in Japan's power sector.

Who This Is For

- **Interested parties:** Build a coherent mental map of Japan's power system and why traders care about frequency, fuels, and market design.
- **Invested parties (e.g. banks & commodity firms):** Understand how Japanese power exposures connect to JKM/API2/TTF and USD/EUR/JPY risk, and why market structure matters.
- **Involved parties (e.g. utility firms employees):** See how external trading desks and consultancies interpret your grid constraints, policy, and demand/supply balance.

How to Work With It

1. **Read the Executive Summary and Key Takeaways**
2. **Use the Frequency Divide and Fuel Mix sections** as you revisit each corresponding slide.
3. **Complete the Quiz** after the videos to test understanding and connect concepts to your role.
4. **Return to the Glossary** whenever you encounter an unfamiliar term.

02 · Executive Summary

The 2026 Trading Frontier

Japan's power market is one of the most complex, volatile, and geographically fragmented energy landscapes globally. As of early 2026, the market has advanced into a mature phase defined by server-to-server API bidding, five-zone intraday trading, and an ambitious but balanced decarbonisation roadmap under the METI Seventh Strategic Energy Plan.

The Plan targets renewables as the major source (40–50% by 2040), nuclear revival to ~20% for stable baseload, and thermal (coal + LNG + oil) reduced to 30–40% — with coal sharply phased down to ~19% within that bracket. The persistent 50/60 Hz frequency divide drives structural basis risk, while heavy reliance on global indices (JKM, API2, TTF) requires layered USD/EUR/JPY hedging strategies.

With global LNG supply growth, JKM is trending lower (~$9–11/MMBtu average forecast for 2026), yet remains sensitive to weather and supply disruptions. The shift to API-only JEPX spot access raises technical barriers — firms without automated systems are increasingly disadvantaged.

03 · Key Takeaways

1. The Hedging Imperative

Japan's power prices link tightly to global fuel indices (JKM, API2, TTF). Even with JKM trending lower in 2026 ($9–11/MMBtu), traders must manage multi-currency exposure (USD/EUR/JPY) to mitigate volatility and protect margins.

2. Infrastructure as Destiny

The 50 Hz (East) and 60 Hz (West) frequency divide create persistent zonal price divergence. Limited HVDC converter capacity — even with the ~300 MW Shin-Sakuma VSC expansion toward a 12.5 GW target by 2030/31 — means power cannot flow freely, driving regional basis risk.

3. Algorithmic Market Access

Since April 2026, the JEPX spot market requires server-to-server API bidding only; the legacy GUI has been retired. This elevates the technology and governance barrier to entry, particularly for smaller firms.

4. Zonal Intraday Migration

As of October 2026, intraday trading operates across five bidding zones. This improves regional price visibility, but requires traders to analyse local surpluses and shortages against converter limits.

5. Strategic Decarbonisation (S+3E)

The METI Seventh Plan targets renewables 40–50% by 2040, while reviving nuclear (~20%) and reducing coal (~19%). The S+3E framework implies more negative pricing events, greater reliance on ancillary services, and new hedging challenges around curtailment.

04 · Japan's Energy Landscape: Road to 2040

The Seventh Strategic Energy Plan (February 2025) sets the long-term direction under the S+3E pillars. The trajectory is clear: more renewables, moderate nuclear revival, and less coal within the thermal bracket.

Power Mix Evolution

Energy Source	FY2023 Actual	FY2040 METI Target
Renewables	23%	40–50%
LNG	37%	~20% (part of 30–40% thermal)
Coal	32%	~19% (sharply reduced within thermal bracket)
Nuclear	8%	~20% (revived baseload)
Other (Oil, etc.)	<1%	Remaining thermal

Why Traders Care

- **More renewables** → increased intraday volatility, more frequent zero/negative prices, and curtailment risk.
- **Reduced coal and evolving LNG** → shifting marginal cost structure and changing hedging relationships to API2 and JKM.
- **Increased nuclear** → more stable baseload, influencing shape risk (peak vs off-peak spreads) and capacity market dynamics.

05 · Critical Market Players

Organisation	Role	Trading Relevance
METI	Architect of energy policy and the Seventh Strategic Plan.	Defines long-run fuel mix, volatility regimes, and incentives for new capacity.
OCCTO	Nationwide TSO coordinator; manages interregional transmission and HVDC converter capacity.	Determines how much surplus/deficit can be shared across regions — and thus how severe price divergences can become.
JEPX	Wholesale spot and intraday exchange. API-only since April 2026; five zones since October 2026.	Where short-term prices are formed and automated bidding strategies must operate.
TOCOM (JPX)	Venue for yen-denominated power futures including Chubu electricity futures (Spring 2026).	Key link between global fuel benchmarks, FX, and JPY power price hedging.
EEX	Launched Chubu electricity futures in December 2025, ahead of TOCOM.	Captured early international liquidity and options products; benchmark for cross-border hedging flows.
Large Utilities	Major buyers of LNG and coal; owners of large generation portfolios.	Their procurement and hedging decisions shape physical flows and market price dynamics.
Trading Desks & Consultancies	Price, structure, and hedge exposures; advise on strategy and risk.	Design and execute strategies tying global indices (JKM/API2/TTF) and FX into Japan's zonal market.

06 · The Frequency Divide & Basis Risk

Japan's grid operates as two non-synchronous frequency systems — a historical accident from the late 1800s never fully unified due to prohibitive cost and complexity.

Zone	Frequency	Region	Historical Origin
East Japan	50 Hz	Kanto, Tohoku, Hokkaido	AEG (German) generators imported late 1800s
West Japan	60 Hz	Kansai, Chubu, Kyushu	GE (American) generators imported late 1800s

The boundary follows the **Fujigawa River** (Shizuoka) and **Itoigawa River** (Niigata). Power transfer between East and West requires HVDC frequency converter stations (Sakuma, Higashi-Shimizu, Shin-Shinano).

The HVDC Bottleneck

- **Shin-Sakuma VSC upgrade:** ~300 MW of additional capacity by March 2028, contributing toward ~12.5 GW interregional capacity by 2030/31.
- Converter capacity remains limited relative to potential surpluses/deficits, especially during high renewable output periods.
- When converters are at capacity, surplus cannot flow freely → regional price decoupling and elevated basis risk.

■ CROSS-FREQUENCY BASIS RISK — KEY CONCEPT

A Tokyo-area (50 Hz) retailer hedging with a 60 Hz-linked futures contract faces imperfect protection when HVDC limits prevent price convergence. This cross-frequency basis risk is a structural, persistent feature of Japan's market — not a temporary anomaly.

Practical Example

A surplus of renewable generation in Tohoku (50 Hz) can drive local spot prices to zero or below. If HVDC converters are already at full capacity, that surplus cannot flow to Kansai (60 Hz), where prices remain elevated. A trader holding a West Japan long position gains nothing from the East Japan surplus — and vice versa.

07 · Fuel Mix & Index Dependencies

Japan is a resource-constrained island system, with power prices highly sensitive to imported fuel costs and their international indexation. Understanding the link between global commodity benchmarks and domestic power prices is foundational.

Primary Benchmarks

Index	Commodity	Currency	2026 Context
JKM	Spot LNG (Japan/Korea)	USD	~$9–11/MMBtu avg forecast; lower than 2025 peaks but weather-sensitive
API2	Coal (Rotterdam)	USD	Referenced in Japanese coal import contracts; links to European markets
TTF	European Natural Gas	EUR	Indirect influence via global LNG arbitrage and JCC-linked contracts
JCC	Japan Crude Cocktail (oil-linked LNG)	USD	Governs legacy long-term LNG contracts; declining relative to spot JKM

08 · LNG Hedging: A Practical Example

Professional trading desks use a layered, multi-instrument hedging chain to manage Japan's compound exposure: commodity price risk (JKM), currency risk (USD/JPY), and power price risk (TOCOM). These three layers must be reconciled against the zonal/frequency structure of the domestic market.

The Three-Step Hedging Pathway

Step	Exposure	Instrument	Purpose
1	Fuel price risk	CME JKM USD futures	Hedge USD-denominated spot LNG price risk
2	Currency risk	USD/JPY FX swaps	Neutralise currency volatility between LNG costs and JPY revenues
3	Power price risk	TOCOM yen power futures	Align hedges with expected power sales prices in domestic markets

■ IMPORTANT NOTE

These three steps must be reconciled against Japan's zonal and frequency-split market structure. A hedge designed around a 60 Hz TOCOM contract provides only partial protection for a 50 Hz load — the residual cross-frequency basis risk must be separately identified and managed.

Case Study

EEX vs TOCOM in Japan Power Derivatives: Timing, Liquidity, and Market Structure (2025–2026)

In December 2025, the European Energy Exchange expanded its Japanese power derivatives offering by introducing Chubu-area electricity futures and related products.[1] This preceded the planned launch of comparable Chubu electricity futures by the Tokyo Commodity Exchange in April 2026.[2] The sequencing of these product introductions is documented in exchange announcements and reflects differing rollout timelines between an internationally oriented exchange and a domestic marketplace.

Prior to the Chubu expansion, EEX had already established a presence in Japanese power derivatives, including the introduction of options on Japanese electricity futures in 2025.[3] In contrast, TOCOM's derivatives suite has been more concentrated in futures contracts, with ongoing efforts to expand participation and improve liquidity conditions.[4] Exchange disclosures further indicate that trading volumes in Japanese power derivatives on EEX have exceeded those on TOCOM in recent periods, although both venues have reported growth.[5]

From a market microstructure perspective, the earlier availability of Chubu contracts on EEX implies that, during the interim period between December 2025 and April 2026, market participants seeking standardized hedging instruments for this region could access such products only on EEX. This represents a **temporal asymmetry in product availability**, rather than direct evidence of liquidity migration. While it is reasonable to infer that some participants active on EEX may have utilized these instruments, the extent and composition of such activity are not publicly disclosed at a granular level.

More broadly, the coexistence of EEX and TOCOM reflects a dual-market structure in Japan's power derivatives ecosystem:

- EEX operates as an internationally integrated venue with cross-border participation and a broader derivatives toolkit, including options.
- TOCOM operates within a domestic regulatory and institutional framework, with closer alignment to local utilities and retail suppliers.

Differences in product timing, participant composition, and liquidity depth are therefore expected, particularly in a developing derivatives market. However, attributing causality—such as asserting that early product launch leads to sustained liquidity dominance—requires transaction-level evidence that is not currently available in the public domain.

Conclusion

The December 2025 launch of Chubu electricity derivatives on EEX ahead of TOCOM's April 2026 rollout constitutes a verifiable instance of asynchronous product introduction. While this timing provided interim access advantages, claims regarding liquidity capture or structural dominance should be interpreted cautiously. The evolution of liquidity between international and domestic venues in Japan's power derivatives market remains an empirical question.

---

09 · Glossary of Key Terms

Term	Definition
API Bidding	Mandatory server-to-server automated interface for JEPX spot market access (April 2026), replacing the legacy GUI. Firms without API infrastructure are locked out of spot trading.
API2	European coal price index (Rotterdam), denominated in USD. Referenced in Japanese coal import contracts and used to calculate dark spreads.
Basis Risk	The risk that a hedging instrument and the actual exposure diverge in price. In Japan, the most structurally significant form is cross-frequency basis risk between 50 Hz and 60 Hz zones.
Dark Spread	The implied margin from generating power using coal: Power Price minus (Coal Price × Heat Rate).
Gate Closure	The deadline after which intraday positions are fixed prior to real-time balancing by the system operator (OCCTO).
HVDC	High Voltage Direct Current. The technology used in Japan's frequency converter stations (Sakuma, Higashi-Shimizu, Shin-Shinano) to transfer power between the 50 Hz and 60 Hz grids.
JCC	Japan Crude Cocktail. An oil price index governing legacy long-term LNG supply contracts into Japan. Declining in relevance relative to spot JKM pricing.
JEPX	Japan Electric Power Exchange. Japan's wholesale spot and intraday electricity exchange. API-only since April 2026; five-zone intraday structure since October 2026.
JKM	Japan Korea Marker. The primary USD-denominated benchmark for spot LNG cargo prices into Japan and South Korea. Published by Platts/S&P Global.
Merit Order	The dispatch ranking of generation units by marginal cost (lowest first). Determines the spot price — the cost of the last unit needed to meet demand.
METI	Ministry of Economy, Trade and Industry. Japan's energy policy architect. Publisher of the Seventh Strategic Energy Plan (February 2025).
OCCTO	Organisation for Cross-regional Coordination of Transmission Operators. Japan's nationwide TSO coordinator; manages interregional transmission and HVDC converter capacity allocation.
S+3E	Japan's energy policy framework: Safety plus three E's — Energy Security, Economic Efficiency, and Environment. Underpins the METI Seventh Strategic Energy Plan.
Spark Spread	The implied margin from generating power using gas: Power Price minus (Gas Price × Heat Rate).
TOCOM	Tokyo Commodity Exchange, part of JPX. Venue for yen-denominated electricity and energy futures in Japan, including Chubu electricity futures (launched Spring 2026).
VSC HVDC	Voltage Source Converter High Voltage Direct Current — the modern converter technology used in the Shin-Sakuma upgrade, offering more flexible power flow control.
Zonal Bidding	The intraday market structure (active October 2026) dividing Japan into five bidding zones for granular, regionally-specific price signals.
